Air Over Hydraulic Brake System Diagram

air over hydraulic brake system diagram is an essential component in understanding the operation and maintenance of modern braking systems, especially in heavy-duty vehicles like trucks, buses, and industrial machinery. This system combines the advantages of both pneumatic (air) and hydraulic braking methods to deliver efficient, reliable, and responsive braking performance. To grasp how this system functions, it is important to examine its components, working principles, and the typical diagrams used to illustrate its operation.

Understanding the Air Over Hydraulic Brake System

The air over hydraulic (AOH) brake system is a hybrid braking mechanism that utilizes compressed air to operate hydraulic brake components. It is designed to provide powerful braking force while maintaining safety and ease of control. This system is particularly common in large commercial vehicles where conventional hydraulic brakes alone may not suffice.

Key Components of the Air Over Hydraulic Brake System

To understand the system's operation, it is vital to familiarize oneself with its main parts:

1. **Air Compressor:** Generates compressed air used for brake operation.
2. **Air Reservoirs (Air Tanks):** Store compressed air to be used during braking.
3. **Control Valve:** Manages the flow of compressed air into the hydraulic system.
4. **Brake Pedal (or Brake Valve):** The operator's input device to initiate braking.
5. **Air Lines and Hoses:** Connect components and transmit compressed air.
6. **Hydraulic Master Cylinder:** Converts hydraulic pressure to apply brake force on the wheels.
7. **Brake Actuators (Calipers or Wheel Cylinders):** Apply force to brake shoes or pads against the drum or disc.
8. **Relay Valve:** Controls the release and application of air pressure to the brake chambers.

Working Principle of the Air Over Hydraulic Brake System

The operation of an air over hydraulic brake system involves

several sequential steps that ensure effective braking:

Step-by-Step Operation

1. **Brake Application:** When the driver presses the brake pedal, it activates the control valve, which allows compressed air from the reservoirs to flow into the system.
2. **Air Transmission:** The compressed air acts on a pneumatic actuator or operates a relay valve, which then directs air pressure to the hydraulic master cylinder.
3. **Hydraulic Pressure Generation:** The pressure from the air actuates the hydraulic master cylinder, converting pneumatic energy into hydraulic pressure.
4. **Brake Force Application:** Hydraulic pressure is transmitted through brake lines to wheel cylinders or calipers, applying the brakes by pressing brake shoes or pads against the drum or disc.
5. **Release of Brakes:** When the driver releases the brake pedal, the control valve vents the air pressure, causing the hydraulic pressure to drop, and springs or return mechanisms release the brake shoes or pads.

This hybrid system ensures that braking is both powerful and controllable, with air providing the initial force and hydraulic components delivering precise application.

Diagrammatic Overview of the Air Over

Hydraulic Brake System

Below is a simplified conceptual description of the typical air over hydraulic brake system diagram: - Air Supply Side: - Starts with the air compressor feeding compressed air into the air reservoir(s). - Air flows through main air lines, passing through control valves (including the brake valve). - Control Valve Section: - The service brake valve or foot valve receives pilot pressure from the brake pedal. - When pressed, it sends an air signal to the relay valve. - Relay Valve & Air Actuation: - The relay valve amplifies the air pressure and directs it to the air chamber connected to the hydraulic system. - This air pressure actuates a piston or diaphragm mechanism. - Hydraulic System Activation: - The piston movement in the air chamber applies force to the hydraulic pump, which pressurizes the hydraulic fluid. - The hydraulic pressure is transmitted to wheel cylinders or calipers, applying the brakes mechanically. - Hydraulic Brake Assembly: - Converts hydraulic pressure into the physical movement of brake shoes or pads against the rotor or drum. - Emergency & Safety Components: - A spring brake chamber may engage if air pressure drops below a threshold, applying brakes automatically. - Emergency valves can vent air or maintain pressure to ensure safety.

Step-by-Step Operation of the System

Understanding how the system functions during actual brake application is pivotal: 1. Initiation of Brake Application: - The driver presses the brake pedal. - This action sends a pilot air signal via the service brake valve. 2. Air Signal Transmission: - The pilot pressure opens the relay valve. - Compressed air from the reservoir flows into the air chamber of the brake actuator. 3. Activation of Hydraulic Pump: - The air chamber pressure acts on a piston, which mechanically activates the hydraulic pump. - Hydraulic fluid is pressurized and sent to the wheel cylinders. 4. Braking Force Application: - Hydraulic pressure pushes the brake shoes or pads against the rotor or drum. - The vehicle decelerates. 5. Release of Brakes: - Releasing the brake pedal vents the air pressure. - The relay valve closes, hydraulic pressure drops, and the brake shoes retract.

Diagram Explanation: Visualizing the System Components

While a visual diagram offers clearer insights, an understanding of the typical layout is essential. Here's an in-depth explanation of what such a diagram entails: - Air Supply Section: - Located at the top or one side, illustrating the air compressor, reservoirs, and principal air lines. - Symbols for air filters, dryers, and pressure regulators may be included. - Control Valve Assembly:
